

Recommendation Package

Methods

- `RecommendationController()`
 - Constructor for initializing the recommendation controller.
- `getEventFeed(accountId: int): List<EventEntity>`
Returns a list of recommended `EventEntity` objects for the given user.

Recommendations are based on:

- User's current location
- Events the user has liked
- User's stored preferences

To access this information, the method calls:

- `getLikedEvents(accountId: int)` – fetches events the user liked
- `getAccountById(accountId: int)` – fetches the user profile and preferences

These methods are provided by the `ProxyDBController`.

- `getLikedEvents(accountId: int)` – retrieves events the user has liked
- `getAccountById(accountId: int)` – retrieves the user's profile and preferences

These helper functions are part of the `ProxyDBController`.
